

Wind frequency range: 0 Hz - 500 Hz

Peak magnitude: ≈ -42 dB

Bird call frequency range: 300 Hz - 7 kHz

Peak magnitude: ≈ -56 dB

⑥

- A low-pass filter only allows low frequencies to get through, so it would filter out all of the bird calls that we want to keep.
- A high-pass filter could be ideal if we can choose the frequency that it starts allowing to be right before the bird calls begin, therefore filtering out the wind.
- A band-pass filter could be useful if we have higher frequencies that we need to cut out alongside the wind's frequencies, but since we don't, a high-pass is more effective.
- A band-stop filter could also work if we altered the stopband to cover 0 Hz - 500 Hz, but at that point it's more convenient to use a high-pass filter.
